

StayNest — Production-Scale Vacation Rental Marketplace Architecture

Architecture covering frontend, backend, storage, search, deployment and scaling

Key design notes

- Browser storage can support the current MVP booking flow; production deployments should move booking, user and availability data to a server-side database.
- Search is separated as a scalable service so location, filters and ranking can evolve independently from the web application.
- Images belong in object storage and should be delivered through a CDN rather than stored directly in the application server.
- Production deployment should use HTTPS, secret management, logging, monitoring, rate limiting and server-side validation.
